

LOGARITHMIC TABLES
OF
NUMBERS AND TRIGONOMETRICAL FUNCTIONS
BY
BARON VON VEGA.

TRANSLATED FROM THE
FOURTH EDITION OF THE GERMAN EDITION
THOROUGHLY REVISED AND ENLARGED EDITION.

BY
W. L. F. FISCHER, M. A., F. R. S.
FELLOW OF ST JOHN'S COLLEGE, CAMBRIDGE, PROFESSOR OF NATURAL PHILOSOPHY
IN THE UNIVERSITY OF ST ANDREW'S

STEREOTYPED. M. KNOTION.

P R E F A C E.

The existing logarithmic-trigonometrical Tables to seven figures may be divided into three classes. While the first class which contains the logarithms of the natural numbers is very nearly the same in all, they differ in the second, or trigonometrical part in this, that the first class contains the trigonometrical functions for the greatest part of the quadrant only for every full minute, the second for every tenth second, and the third for every single second. The oldest logarithmic table to seven figures belongs to the first class, viz. that of Sherwin, London, 1705. It contained the logarithms of the numbers from 1 to 101000 and besides the sines, tangents and secants, also their logarithms from minute to minute. This table had run through several editions by the end of the last century and served till quite recently as the basis of innumerable logarithmic tables, in some of which the natural sines and tangents, which are little wanted, were omitted, while others of them were enriched by more or less useful additions. Gurdiner, who in the year 1741 prepared a third edition of Sherwin's table, constructed at the same time a table proceeding from 10 to 10 seconds, which was the first of its kind, and was published in London in the year 1742 in large 4^{to} 1). A second edition of this table also in large 4^{to} with the addition of the logarithms of the sines and tangents for every single second up to 4^o was published at Avignon in 1770 2). Upon these were founded Callet's "tables portatives" which were first published at Paris in 1783 and afterwards stereotyped. On account

1) Tables of Logarithms.

2) Tables de Logarithmes.

of their more convenient shape they soon displaced the former tables, and maintained the preference up to the most recent time. The first table of the third kind is the large one by Taylor published in London in 1792. Bagay's tables¹⁾ founded upon it and published at Paris in 1829, appeared in a much smaller form in consequence of the smallness of the figures. To the tables of the first and second class belong also the logarithmic tables to seven figures calculated for the centesimal division of the quadrant, as that by Hobert and Ideler²⁾ proceeding from 100^{th} to 100^{th} of a grade (centesimal degree), and that published by Delambre³⁾ in the year IX. of the republic, in which the interval is ten times as small, viz. 10 centesimal seconds.

For tables to five figures the interval of one minute may be considered the proper one, because the differences will not be too large to admit of the proportional part for seconds being mentally calculated with readiness. In tables to seven figures this interval has always been recognized as highly inconvenient, on which account Gardiner directed his attention to the diminution of the interval. It is even necessary to diminish the interval to one second, if it be made a condition that the proportional part in this case too is to be mentally calculated. This very small interval, however, gives rise to several new inconveniences, which diminish the advantage of smaller differences to such a degree, that tables of this kind have never come much into use, at least with professional computers. Their large form, the excessive number of columns on every page, and the circumstance that even then there is not nearly room enough for all the figures, (the initial figures of the logarithms having to be placed at the top of the columns and the differences altogether omitted, so that they must be calculated by the computer,) make the advantage of the smaller interval very questionable.

The editions of Vega's *Logarithmic Tables* hitherto published had, in the trigonometrical part, the interval of 1 minute. In the present revised edition care has been taken not only to adopt the interval of 10 seconds for the whole quadrant in order to assign a higher rank to the tables, but also to secure all those ad-

vantages which by attention to size and arrangement might in any way contribute to facilitate the looking out of logarithms. Although the tables have in consequence been considerably enlarged, the price has not been raised, so that the advantages of the enlarged edition are offered to purchasers at a cost, which is unexampled for a work of this kind.

Among the improvements in these tables we may mention:

1. The *systematic arrangement* of all the pages of each section, which has for its object that, when once the book is opened at the proper page, the eye with very little practice will involuntarily be directed to the place where the required logarithm is to be found. For nothing so much increases the difficulty of using tables as a want of uniformity in the position of the numbers. To attain this end main and sub-divisions have been introduced, which are easily distinguished and afford resting points to the eye. In the first part there are four such resting points on every page, viz. on the left page the lines corresponding to the numbers 10, 20, 30 and 40 are enclosed in double rules; on the right page, those corresponding to the numbers 60, 70, 80 and 90. The intermediate lines, opposite to the numbers 1 up to 9, are again separated by narrow spaces into groups of three each. In the second part each page contains 61 lines. Since five principal divisions are thus formed, the third, which is opposite to the number 30 either from the top or from the bottom, is marked by stronger lines, the subdivisions remaining the same as in the first part. Finally in the third part the lines corresponding to full minutes are enclosed between double rules, and every fifth minute is marked by thicker rules. This arrangement which was first employed in a table of six figures¹⁾, has at the same time the advantage, that both with ascending and descending arguments, as in the 2nd and 3rd part, the rules have always the same position relatively both to the right and left margin of the page, an advantage which was unattainable with the single horizontal lines hitherto in use.

2. The *type*. On several occasions Mathematicians and Astronomers have remarked, that the strangely shaded and equally high figures that have become the fashion during the last twenty years, though they present on the whole a better appearance on the page, are yet far less legible than the older ones. Moreover the new

1) *Logarithmorum VI decimalium nova tabula Berolienensis.* Berlin, 1852.

type is easily injured in the finer strokes so that 1 and 4; 0, 6 and 9; 3, 5 and 8 become almost indistinguishable. Besides it often happens, that a figure thus strongly shaded, which dazzles the eye by its very blackness, does not leave sufficient blank space, the figures being both too close to each other and to the rules which mark the intervals. All these circumstances render the use of the tables more difficult and more fatiguing to the eye. Hence a type has been chosen which, being extremely slightly shaded, approaches the older form, projects partly above and below the parallel lines which inclose the main body and does not cover the white ground too much, while it is of a size which is neither too small to be easily recognized by moderately strong eyes, nor too large to get the requisite quantity into a moderate compass. The founding of this type is so characteristic that even after slight injuries which are inevitable after long use, there will be little fear of mistakes. Special attention has been paid to the proper distribution of the space which the figures and rules occupy; and the size of the page was not fixed upon till after repeated trials, and after all circumstances had been taken into account for facilitating the use of the tables.

3. In the trigonometrical part there is frequently a column next to that of the degrees, minutes and seconds, expressing the same are in time; there are also in the first part one or two columns more which give the number, or the number increased ten fold, considered as a number of seconds expressed in degrees, minutes and seconds. This and similar other arrangements have here been omitted, as double and triple arguments, which are not out of place in nautical tables, but tend to obstruct the simple use of a table to seven figures without affording any equivalent advantage. On the other hand, in the first part at the foot of the page the twofold reduction of the argument into arc has been indicated, together with the logarithms of $\frac{\sin x}{x}$ and $\frac{\tan x}{x}$ from 10 to 10 seconds, from 0 to $2^{\circ} 46' 40''$. The latter are required for passing from logarc to logsin and logtan, and are of particular value in geodetic calculations, where long operations have sometimes to be performed with small arcs which are usually expressed in seconds, while four or five decimal places of the second have to be retained.

To facilitate the interpolation, small tables of proportional parts

have been added in the first and third parts. The use of smaller type has enabled us to give them completely even in the first pages for every difference. These tables give accurately the tenths of the whole differences, so that the addition of the tenths, hundredths and thousandths gives the proportional part correct to the last figure, which is not the case with the usual arrangement. According to a very common arrangement the same small table of proportional parts has to be used for the whole extent of the table in its vicinity, without reference to the difference whether it be an unit more or less; but this has been rejected as inaccurate. In the third part want of space has prevented all the differences from being given; at the commencement, i. e. beginning at h° , those only could be inserted which differed by 10 units, then those differing by 5, by 3 etc., while finally, from 24° , each difference is set down. The advantages which these tables afford in interpolation, will be best appreciated by those, who have felt their want in all other tables.

Special attention has been paid to the correctness of the seventh decimal place. Since the accurate value of a logarithm, unless it be a whole number, is always an interminable decimal fraction, the part which follows the first seven figures necessarily amounts to more or less than five units of the 8th decimal place. In the former case the number in the seventh place must be increased by one unit, in the latter not, in order that the tabular value may always differ by less than half an unit of the last place from the true value of the logarithm. Therefore in order to set down the seventh place correctly, a knowledge of the following figures is required. A comparison with Vega's *Thesaurus logarithmorum*¹⁾ left only those logarithms of numbers doubtful, whose logarithms to ten figures ended with 5000; these were therefore recalculated to fifteen places. The tenth figures proving accurate throughout, even in many other cases where the computation was repeated, it was found unnecessary to recalculate the logarithms ending in 499 and 501. The case was however far different in the trigonometrical section. Here the *Thesaurus logarithmorum*¹⁾, with the exception of a few cases as indicated by Vega himself and referring to that part of the table in which the interval is 10 seconds, can hardly be considered as anything but a reprint from

1) *Thesaurus logarithmorum completus*. Lipsiæ, 1794.

been corrected, (most of them being reprinted unaltered), the editors of tables have taken its correctness for granted, either to avoid the trouble of a strict examination, or confiding in the accuracy implied by the offer of a duet for the detection of every error, no similar reward having ever been previously offered. This affords the only explanation of the fact, that in more recent tables several logarithms have been brought back to the erroneous values which follow from Vlack's table, though they are correctly given by Gardiner. Thus 1) the $\log \sin 2^{\circ} 20' 30''$, whose accurate value is 8.63919705001389 has with Gardiner 4 in the seventh place which is correct; but since Vlack and Vega give the \log to ten figures 6391970499, we find in the recent tables and also in Taylor 0 in the seventh place. 2) $\log \tan 2^{\circ} 2' 30''$ is 8.95296824994086; Vlack and Vega give 9529682499; Gardiner gives 2 in the seventh decimal place; the more recent tables, including Taylor's give 3. 3) $\log \tan 7^{\circ} 23' 30''$ is 9.11338844994091; and therefore 5 is the correct figure in the seventh place, but Vlack and Vega have 1133884499, whence the recent tables including Taylor's give 4. 4) $\log \tan 7^{\circ} 53' 0''$ is 9.14688494994092, therefore 9 is the correct seventh figure; but Vega and Vlack have 1468849501, and the modern tables have consequently 10 as the last two figures. 5) $\log \sin 20^{\circ} 40' 0''$ is 9.55716284994091, but in Vlack and Vega 5371628499; Gardiner gives 9, the modern tables 8 in the 7th place.

The second edition of Gardiner published in the year 1730 at Avignon contains besides all the logarithms of the first edition, which were adopted without alteration¹⁾, the logarithms of the sines for every second from $72'$ to 1° , and $\log \tan$ for every second from 0 to 4° . The logarithms thus added have not the same degree of accuracy as those transferred from the older table, though their correctness is still such as might well have served as a pattern for later tables. For a comparison showed that out of 22032 logarithms only 22 were wrong by an unit. Both these additions are in large 4th, which renders them suspicious. For this reason and in consequence of Gardiner's tables becoming scarce, Callet edited a new logarithmic-trigonometrical table, which was printed by Firmin Didot, and was the first, in which the printing

1) A few false prints, discovered during the 28 years that the tables had been used, were corrected, but many new errors were introduced.

from plates was successfully carried out. Besides a long introduction on the calculation and application of logarithms, tables of the natural sines and cosines, tangents and cotangents, and natural and common logarithms of numbers to 20 and 60 figures, this edition contained all the logarithms of the Avignon edition, with this addition that the log sin and log tan for every second which the latter contained up to $4''$ were carried one degree further. But in this enlargement, the degree of accuracy introduced by Gardiner is utterly neglected. A comparison with this part of the tables which contains 6480 logarithms not occurring in Gardiner gave 1368 logarithms inaccurate by an unit in the last place. Finally the last figure of each of the 36000 logarithms of the second part was compared with Taylor's table, which is generally considered as a pattern of accuracy in the last figure, and every deviation thus found was subjected to a separate investigation. This examination gave 35 cases, in which the last figure in Taylor is wrong by an unit; of these 19 coincide with the erroneous statement in the Avignon edition.

A comparison of the logarithms of the first part with Babbage's most carefully edited table, in which elementary principles regarding the construction of tables were first established, furnished one case, that of $\log 52043$ which, as in Gardiner, was given too great by an unit. The same error occurs also in the tables of Callet, Taylor, Delambre and others, evidently because all have copied Gardiner without farther examination.

The first two proofs of this table were corrected by MM. Lanténach, and Gleditscher, and a third revision was instituted by myself, and checked by differences. After they were stereotyped the proofs from the plates were revised partly by Mr. Volkmann, and partly by Mr. Koch.

Berlin, August 1850.

BREMIER.

a number of five figures in the integer part from the given number either by annexing cyphors or by separating the first five figures; find the fractional part of the logarithm of this number, and give an index less by one unit than the number of figures in the integer part of the given number. The index of a proper fraction is found by subtracting the number of cyphers between the decimal point and the first significant figure from 9.

Given a logarithm, required the corresponding number.

A logarithm being given, and it being required to find the corresponding number, we first look out the first three figures of the decimal fraction in the logarithm in the column headed 0, and then in the columns headed 0, 1, 2 . . . those four figures, which are next less than the remaining four figures of the given logarithm. We now take out from the vertical column headed N the number consisting of the four figures, which are on the same horizontal line that contains the last four figures, and as fifth figure, the one at the head of the column. For example, if the logarithm 2.5883980 be given, we find at p. 62 the logarithm 588 3915, to which corresponds the number 38317. The difference between it and the next greater logarithm is 118, whilst the difference between it and the given logarithm is 65. Now the figures following the first five places are found by dividing 65 by 118, that is to say, the next figure is obtained by taking this fraction 10 times, the two next by taking it 100 times, the three next by taking it 1000 times. It would be inexpedient to take more, because even the third figure is uncertain. But this division may be facilitated by the table of proportional parts headed 118. We take from it the next figure 5 corresponding to 56.5 which is next inferior to 65; subtracting 56.5 from 65, there remains 8.5. Taking this tenfold, which gives 85, we find opposite to the next inferior number 79.1 the number 7 as the next figure in the number, and again increasing the difference $85 - 79.1 = 5.9$ tenfold, which gives 59, and looking for the next inferior number in the table (which is 56.5) we find the figure 5, hence the figures following the first five are 575, and the number is written with the figures 38317575; and since the given logarithm has the index 2, the decimal point must be put after the third figure; therefore the required number is 383.17575. The index, however, might have any other value, the number would still consist of the same figures, only the pe-

sition of the decimal point would change; thus if the logarithm were 9.5833980, the corresponding number would contain an integer part of 10 figures. But since the tables furnish only the first eight figures of the number, as found above, two cyphers must be annexed, giving the number 3831757500. If the logarithm were 7.5833980—10, the corresponding number would be 0.0038317575. Hence the computation of the proportional part which with a little practice and by making use of the small table of proportional parts may be made mentally, (so that no other figures need be written down than those actually sought), would stand thus:

$$\begin{array}{rcl}
 \text{Given logarithm} & & 2.5833980 \\
 \text{pag. 62. number 383.17} & . . & 2.5833915 \\
 & & \hline
 & & \text{Difference 65} \\
 \text{by the table for the difference 113} & 5 & 56.5 \\
 & & \hline
 & & 85 \\
 \text{again} & 7 & 79.1 \\
 & 5 & 59 \\
 & & \hline
 \text{required number} & = & 383.17575
 \end{array}$$

In logarithmic calculations cases occur, in which the logarithm of a logarithm has to be taken. If for example a number is to be raised to a power, whose exponent is a number of many figures, or a similar root has to be extracted, we should have to multiply or divide the logarithm of the given number by another large number; but this is again best done by the aid of logarithms. As a first example let it be required to raise the number 23.90087 to the power 1.1087023; here we take the log of 23.90087 which is = 1.3784137; and this must be multiplied by 1.1087023; hence we add the logarithms of both the numbers

$$\log 1.3784137 = 0.1393796$$

$$\log 1.1087023 = 0.0448149$$

$$\log 1.5282504 = 0.1841945$$

and look out the number 1.5282504 corresponding to their sum. This is the logarithm of the required power; hence this power is the number, corresponding to this logarithm, viz. 33.748186. Again, to take a second example, required the 7.001705th root of 0.791; here we should have to divide the log of 0.791 which is 9.8981765—10 by the index of the root. Now in this case the dividend is a difference, and it is simpler to restore the negative logarithm

and to divide it than to divide the two terms of the difference separately, and to get the quotient by the subtraction of the results. Now the negative logarithm is $= -0.1018235$; hence

$$\log 0.1018235 = 9.0078480 - 10$$

$$\log 7.001705 = 0.8452038$$

$$\log 0.0145427 = 8.1626442 - 10$$

Corresponding to the difference $8.1626442 - 10$ we find the number 0.0145427, which is the logarithm of the root; but it is negative, since it has arisen out of the division of a negative logarithm by a positive number; hence the tabular-logarithm is $10 - 0.0145427 - 10 = 9.9854573 - 10$ and the corresponding number is -0.9670687 which is the required root.

TABLE II.

Table II, (p. 188 to p. 287) serves to find $\log \sin$ and $\log \tan$ of arcs not greater than 5° , or the $\log \cos$ and $\log \cot$ of arcs lying between 85° and 90° . The left hand page of the table contains the logarithms of the sines of arcs between 0 and 5 degrees. Degrees and minutes are given at the top, the seconds on the left hand margin. These logarithms are at the same time the logcos of the complementary angles, the degrees and minutes of which are indicated at the bottom of the page, the seconds on the right hand margin. Thus according to p. 210 $\log \sin 1^\circ 11' 46'' = 8.3196173$, which is also $\log \cos 88^\circ 48' 14''$. The right hand page is constructed exactly similarly with regard to $\log \tan$ of arcs between 0 and 5° and $\log \cot$ of arcs between 85° and 90° .

Given an arc, required its $\log \sin$ or $\log \tan$.

For every full second the $\log \sin$ and $\log \tan$ are given in the table. If the arc contains additionally a fractional part of a second, the proportional part has to be calculated in the same manner as for the logarithms of numbers. For this purpose, the logarithm corresponding to the integer part of the seconds in the given arc is subtracted from the \log corresponding to the next full second, or *vice versa*, the difference is multiplied by the fractional part of the second in the given arc, and the product added to, or subtracted from the former logarithm, according as the logarithms go on increasing or decreasing; the former being here the case for descending arguments and the latter for ascending

arguments. Thus let it be required to find $\log \sin 2^\circ 19' 49''.71$. At page 234 we find $\log \sin 2^\circ 19' 49'' = 8.6091653$, differing from the next greater log of $\sin 2^\circ 19' 50''$ by 518, which multiplied by 0.71 gives 367.78 instead of which we take 368. Adding this proportional part to the preceding logarithm we get 8.6092021 as the required $\log \sin 2^\circ 19' 49''.71$.

As a second instance let us find $\log \cot 86^\circ 53' 11''.374$. According to p. 251 this log lies between 8.7355695 and 8.7355307 the difference of which is 388; multiplying this by 0.374 we get 145 which has to be subtracted from the former of these logarithms since they decrease for ascending arguments; hence the required log is 8.7355550.

Given the log sin or log tan of an arc, required the arc.

The process of finding the arc corresponding to a given log sin or log tan by means of table II is exactly the same which is adopted in finding the number corresponding to a given logarithm in table I. We look out the logarithm either next above or next below the given one, according as the logarithm increases or decreases with the increase of the arc; form the difference between it and the given logarithm, and divide it by the whole difference between the two consecutive logarithms of the table between which the given log lies. The quotient is the fractional part of a second which has to be added to the whole number of seconds contained in the arc corresponding to the logarithm, from which we had started; for example let 8.5139150 be the given log cos. The next greater log of the table is according to page 224, 8.5139642, differing from the given one by 492, but from the next smaller one in the tables by 645; hence the arc is that corresponding to the preceding logarithm, which is $88^\circ 7' 43''$ increased by $\frac{492}{645}$ or $0''.763$, i. e. $88^\circ 7' 43''.763$.

When a calculation refers to arcs under 30 minutes, and it is required that the seventh decimal place of the logarithms shall be perfectly accurate, a condition which occurs in higher geodesy, we have to take into account five decimal places in the seconds in passing from the arc to log sin and log tan, or *vice versa*. In this case the use of table II becomes inconvenient both in consequence of the long multiplications and divisions in calculating the proportional parts, and because it would be necessary

to take into account second differences. Here the application of table I is preferable. To find from it the logsin or logtan of an arc, convert it into seconds, take the log of the number of seconds, and add to it the corresponding value of S or T, given at the bottom of the page, each of which begins with 4.685. Thus if it be required to find logsin and logtan of $22^{\circ} 17' 7083$, we have (see p. 13)

$$\log 1377.7083 = 3.1391573$$

$$S\ 22^{\circ} 18'' = 4.6855716$$

$$T\ 22^{\circ} 58'' = 4.6855813$$

$$\log \sin = 7.8247289$$

$$\log \tan = 7.8247386$$

where in interpolating we have only to take account of whole seconds. If the arc were $137^{\circ} 777083$, we should as before take log arc from p. 13, but the numbers S and T with the argument $2^{\circ} 18''$; from p. 2; thus we should have

$$\log 137^{\circ} 777083 = 2.1391573$$

$$S\ 2^{\circ} 18'' = 4.6855716$$

$$T\ 2^{\circ} 18'' = 4.6855749$$

$$\log \sin = 6.8247321$$

$$\log \tan = 6.8247322$$

If conversely, it be required to find the arc corresponding to a given logsin or logtan, we first take the arc to the nearest second below from table II, and look out in table I the corresponding values of S and T; we subtract these from the given logarithm and take out the number corresponding to the difference, which gives the required arc in seconds. Thus let 7.1690522 be a given logtan. According to p. 139 the corresponding arc lies between $5^{\circ} 4''$ and $5^{\circ} 5''$; at p. 3 the value of T is 4.6855752, hence

$$\log \tan \quad . \quad . \quad . \quad 7.1690522$$

$$T\ 5^{\circ} 4'' \quad . \quad . \quad . \quad 4.6855752$$

$$\text{Difference} \quad 2.4834770 = \log 304.4227$$

hence arc = $304''.4227$ or $5^{\circ} 4''.4227$.

In this method it would be necessary to refer to two or even three different places of the tables; to avoid this inconvenience a table has been added at p. 575 which for arcs up to 35° gives with much more readiness all transitions between S, arc and log sin as well as those between T, arc and logtan. For extensive geodetic calculations this table may be taken out of the book and mounted on cardboard, to be used as an auxiliary table, besides

which we require only the table of logarithms of the numbers of the seconds in the arc. In regard to the construction of this table, it is to be observed, that the value of $S = 4.6855749$ holds up to $1' 39''$ and $\log \sin 6.681$. From $1' 40''$ or $\log \sin = 6.682 \dots$ the succeeding value of $S = 4.6855748$ is to be used. All other values of S answer accurately to the arcs and $\log \sin$ on the same line with them, so that in passing from the arc or $\log \sin$ to the number S that value of S has to be taken, which lies nearest to the given arc or $\log \sin$. The same rule holds for T . Hence, except for a few values of S and T towards the end of the table which increase by 10 units at a time, all interpolation is avoided, as with a glance at the table we can at once take out the required S or T .

TABLE III.

This table contains for every ten seconds of the quadrant the logarithms of the sines, cosines, tangents, and cotangents. From 0 to 45° the degrees are placed at the top of the page; the minutes and seconds, denoted with ' and " on the left hand margin, which is to be combined with the heading at the top of the page. From 45° to 90° the degrees are put at the bottom of the page, the minutes and seconds at the right hand margin, and the name of the trigonometrical function at the foot of the column. Arguments that are opposite one another are complementary (i. e. make together 90°) and the sines and tangents (i. e. their logarithms) of an arc above 45° are also placed opposite to the sines and tangents of its complement, because the former are respectively the cosines and cotangents of the latter, and *vice versa*. For the sake of symmetry the sine is placed next to the argument, next to it the tangent, which is followed by the cotangent, and this by the cosine; and since for complementary angles the same logarithms hold, but in an inverse order, there is again next to the argument the sine, followed in order by the tangent, cotangent, and cosine, as may be seen by the names at the top and bottom of the columns. The differences of any two consecutive logarithms are placed for the sine and cosine immediately to the right on the intermediate line, and are headed *d* (differentia); for the tangents and cotangents they are also placed between these columns on the intermediate line and are headed *d. o.* (differentia communis) since these differences hold for both. The sines

and cosines of all arcs in the quadrant are proper fractions, and so are the tangents for arcs below 45° ; hence their logarithms would be negative. But the index and the fraction have been made positive by the addition of 10, so that -10 has to be supplied. For tangents of arcs between 45° and 90° this supplement must be omitted.

Given an acute angle, required its sine (logsin).

As the table contains the sine only for every tenth second, we have to interpolate for the units and its decimal parts. This is done, as in the case of the logarithms of numbers, by multiplying the decimal fraction formed by the tenth part of the units with the appended fraction by the difference, and adding the product to the logsin of the next inferior multiple of $10''$; for example let it be required to find logsin $18^\circ 14' 27''.21$. Here the sine of $18^\circ 14' 20''$ is 0.31004401, which differs from the next in the table by 0.16; multiplying this by 0.721 we get 0.115, which added to the preceding logarithm gives 0.31005556, the number required. The formation of this product, when no separate auxiliary table of proportional parts¹⁾ is employed, is facilitated by the small tables of differences on the margin. Since for want of space it has not been possible to put down all these differences we in every case take the nearest; in the present instance we take that for 0.14. It gives

for 0.7	429.8
for 0.02	12.3
for 0.001	0.6
together		442.7

But since the difference 0.16, is greater by 2 than 0.14, we have to add $0.721 \times 2 = 1.4$, which gives 444 as the proportional part. Similarly we might have made use of the table headed 0.17 on the left hand page, which would have given 444.9 and from this we would have had to subtract 0.721×1 i. e. 0.7, so that the result would have been the same.

Given an acute angle, to find its tangent (logtan).

The logarithms of the tangents like those of the sines go on

1) Bremker, *Tafel der Proportionaltheile* (Table of proportional parts). Berlin, Ferd. Dümmler, 1843.

increasing as the arc increases from 0 to 90° , so that the proportional part has again to be added. Its computation is exactly like that for the sine: the tenth part of the number formed of the units and the decimal part of the seconds is multiplied by the whole difference and the product added to the logtan of the next inferior arc in the table, and here again, if better means are wanting, recourse may be had to the small difference tables in the margin. Thus let it be required to find logtan $56^\circ 22' 3''.89$. At page 491 we find logtan $56^\circ 22' 0'' = 0.1770234$, differing from the next greater tangent by 457 (a difference found above the logarithm since the argument is ascending). The small table for 457 gives

for 0.3	. . .	137.1
0.08	. . .	36.6
0.009	. . .	4.1
for 0.389	. . .	177.8 or 178

Adding 178 to the preceding log, we find 0.1770412 the required logtan.

We may here observe, that a computer who has had some little practice, shortens the calculation of the proportional parts very materially; and in the last example he would not write down any figures excepting those in the required logarithm. He would proceed in the following manner. Having opened the book at the proper page, in this case p. 491, he points with a finger of the left hand to logtan $56^\circ 22' 0''$. A glance shows, that 457 is the proper difference. (A practised computer in order to avoid the risk of a mis-print will verify at the same time, that this is really the difference of the two logarithms standing one above the other.) Keeping the finger of the left hand pointing, he takes from the small table headed 457 with the argument 0.389 first 4.1 for the last figure 9; this he adds mentally to 36.6, which corresponds to the second figure 8; this again gives 40.7, which is added to 137.1, which number is opposite to 3. The sum 177.8 for which 178 is taken, is added to the last four figures 0234 of the logarithm, to which the finger points; this gives 0412 as the last four figures of the required log. These are finally read together with the first figures 0.177, and written down in their proper place on the paper on which the calculation is made. The mental calculation is much facilitated by acquiring the habit of forming the sums of two numbers not as usual from right to left, but from left to right, which has

the advantage of giving the last four figures of the logarithm in this order, and enables the calculator to write down from left to right the whole logarithm, consisting of eight figures. Reading sums and differences of two logarithms placed one above the other from left to right has in general many advantages in calculations, both because it is more convenient to write from left to right, and because we may use the number thus read as the argument for looking out the corresponding arc, without writing down the number itself, which is frequently no further needed.

Given an acute angle to find its cotangent.

The logarithms of the cotangents and tangents of the same arc always have the same sum 10, or properly 0, since we have mentally to supply either to the *tan* or *cot* the number - 10. Hence the cotangents continually decrease as the arc increases from 0 to 90°, and the proportional part which has to be calculated with the same difference as the tangent must be subtracted. Thus let it be required to find *logcot* 14° 55' 18".92. At page 270 we find first the logarithm 0.5743969 as *logcot* 14° 55' 10" with the difference 846. The small table for the difference 846 gives for 8.02 the proportional part 677.7, which on account of the difference being greater by 1 has to be increased by 0.8, giving 678.5; this subtracted from the above number leaves 0.5743281 the required *logcot*.

Given an acute angle, to find its cosine.

The *logcos* is found in the same manner as the *logcot*, because it, too, decreases continually with the increase of the acute angle. If the angle is 45° 41' 44".25, we subtract from *logcos* 45° 41' 40" which is 0.8441669 with the difference 216 (see p. 55b) the product of 0.425 × 216, i. e. 92, which gives the required *logcos* = 0.8441477.

Given a logsin, cos, tan or cot, required the corresponding acute angle.

When the acute angle corresponding to a given logarithm of a trigonometrical function has to be found from the table, two cases must be distinguished, according as the logarithms and arcs do or do not increase simultaneously. In the former which is that of the sines and tangents we look out the next smaller logarithm, subtract it from the given one and divide this difference

by the whole difference between it and the next greater logarithm in the table. The quotient being put in the form of a decimal fraction, the decimal point is moved one place to the right, and the result will be the number of units and parts of an unit of a second, which have to be taken together with the arc corresponding to the log from which we started. The division may be executed by the aid of the tables of differences. Example: log sin being 9.8725738 we find at p. 540 the next smaller log sin 9.8725654, corresponding to the arc $48^{\circ} 13' 10''$, and differing from the given log by 84, whilst the whole difference is 188; now a glance at the small table headed 188 shows that 84 contains 0.4, and opposite 4 the table gives 75.2, the number next below 84, and differing from it by 8.8. These, according to the same table, give 0.04 with a remainder 1.3, because 7.5 corresponds to .04; this remainder 1.3 gives .007 more; hence the whole decimal fraction is 0.447. Moving the decimal point one place to the right, we got 4.47 as the number of seconds which, added to $48^{\circ} 13' 10''$, give $48^{\circ} 13' 14''.47$ for the required arc.

Should the margin not contain a difference table for the whole difference we may make use of the one calculated for the next greater or smaller number, provided only we increase or diminish the numerator of the required fraction in the same proportion. Let the given fraction be $\frac{P}{Q}$, and let the table for $Q \pm q$

be used; it suffices to take instead of P the number $P \pm \frac{P}{Q}q$ and use this as argument. Thus if there be given $\log \tan = 9.2632000$, the next smaller $\log \tan$ (see p. 352) is 9.2631240, and the difference 760 has to be divided by 1188. If now the table for 1180 be used, we must take $760 - \frac{760}{1188} \times 8 = 760 - 5 = 755$ instead of 760; and corresponding to this we find by the table 0.640. Similarly we might make use of the table for 1190, in which case we must increase 760 by $2 \times \frac{760}{1188}$ or by 1; and corresponding to 761 the table for 1190 gives the same result, viz. 0.640. Hence the arc corresponding to the given $\log \tan$ is $10^{\circ} 23' 16''.40$.

When the logarithms decrease with the increase of the arc, which is the case with the cot and cos, the next greater logarithm is looked out, from it the given one is subtracted and this diffe-

rence divided by the whole difference; the rest of the process remains as before. For example let $\log \cos = 9.7107395$; at p. 475 we find $\log \cos 59^\circ 5' 10'' = 9.7107512$ which is next greater than the given one, differing from the given log by 117, whilst the whole difference is 352, and by the small table for 352 we get $\frac{117}{352} = 0.332$; hence the arc is $59^\circ 5' 13''.32$.

When the sines are to be determined for an angle exceeding 90° , we subtract from it one, two, or three right angles as the case may be, and take the sine of the remaining acute angle when two right angles have been subtracted, but take the cosine when one or three right angles have been subtracted. It is to be observed, besides, that the sines are negative in the third and fourth quadrants, which is denoted by an n annexed (as an index) to the logarithm. In like manner $\log \cos$ of an angle exceeding 90° is found by first taking from it one, two, or three right angles, and then determining respectively the sine, the cosine or the sine of the remainder, and observing that the cos is negative in the second and third quadrants, which again is indicated by annexing an n to the logarithm. For tangents and cotangents which are negative in the second and fourth quadrants the same interchange has to be made, when 1 and when 3 right angles have been subtracted. These relations are shown in the following tabular form, in which z represents an angle in the first quadrant, so that $90^\circ + z$, $180^\circ + z$ and $270^\circ + z$ lie in the second, third, and fourth quadrants respectively.

arc	sine	cosine	tangent	cotangent
z	$+\sin z$	$+\cos z$	$+\tan z$	$+\cot z$
$90^\circ + z$	$+\cos z$	$-\sin z$	$-\cot z$	$-\tan z$
$180^\circ + z$	$-\sin z$	$-\cos z$	$+\tan z$	$+\cot z$
$270^\circ + z$	$-\cos z$	$+\sin z$	$-\cot z$	$-\tan z$

From this table it appears conversely, that corresponding to a given value of every trigonometrical function, when its algebraic sign is unknown, four different arcs in the first four quadrants may be found; and two when the sign is given. If for example a $\log \cos$ with n annexed is given, so that the cosine is negative, this taken positively may be looked out in the column of the cosines, when 180° have to be added to the corresponding

acute angle; or it may be found as the sine of an acute angle which increased by 90° has the given cosine. For an arc to be completely determined by a trigonometrical function we require, besides the sign of this function, also that of any other trigonometrical function of the same arc, provided the two are not tan and cot, or we must know from other sources in what quadrant the arc lies. Trigonometrical calculations are usually so arranged, that for the determination of an arc the logarithms of two numbers, respectively proportional to the sine and cosine, with their proper signs are finally obtained, so that no doubt remains as to the quadrant. For if the logarithms of a $\sin A$ and a $\cos A$ are given, their difference is $\log \tan A$, and A lies in the first or third quadrant, according as $\sin A$ and $\cos A$ are either both positive or both negative, the tangent being positive; or A lies in the second quadrant, when $\sin A$ is positive, and $\cos A$ negative; finally A lies in the fourth quadrant when $\sin A$ is negative and $\cos A$ positive, in both which cases $\tan A$ is negative. Hence in the first case (when $\tan A$ is positive), the logarithm is looked out amongst the tangents, and the corresponding acute angle is taken out, or that angle increased by 180° ; in the second case, when the tangent is negative, we look out the log in the column of cotangents, take out the corresponding acute angle and increase it by 90° or 270° respectively. The angle A being found, the subtraction of $\log \sin A$ from the first or of $\log \cos A$ from the second number gives $\log a$. The following examples will serve to illustrate these rules.

$\log a \sin A$	8.0857112	9.5028101	1.8839108 n	8.1158505 n
$\log a \cos A$	2.7120088	9.6729909 n	2.0057687 n	7.9210259
$\tan A$	0.3727024	9.8298192 n	9.8781421	0.1948246 n
A	$67^\circ 1' 34'' .65$	$145^\circ 56' 56'' .80$	$217^\circ 3' 54'' .67$	$302^\circ 38' 32'' .76$
$\sin \left. \begin{matrix} \sin \\ \cos \end{matrix} \right\} A$	9.9641106	9.9183138 n	9.9019759 n	9.9257435 n
$\log a$	3.1216006	9.7546771	2.1087928	8.1901070

In these examples a has been regarded as positive; if a is assumed to be negative, the arc A will change by 180° ; the $\tan A$ which serves only as argument need not have been written down in the preceding calculation.

1) Before using the table, a correction is required for the height of the barometer. This correction depends upon the attached thermometer, and is taken with the argument $t-t'$ from the small table at p. 564.

Before using the table, a correction is required for the height of the barometer. This correction depends upon the attached thermometer, and is taken with the argument $t-t'$ from the small table at p. 564.

ARGUMENTS: CORRECTED BAROMETER¹⁾ AND MEAN REFRACTION CORRECTED FOR TEMPERATURE BY TAB. II.

Example

App. Alt. 11° 18' 0"
Barom. 28.31 Engl.
Therm. external 85° Fh.
" attached 70

Reduction (see p. 563.)
Barom. 28.25 . . . 26.6

Therm. 85° = 83.75 + 1.25 = 23° + 0.44

23° 55' = 23.6°
70° = 68° + 2° . . . 16° + 0.89
= 16.89° = 16.9° = 1'

1 - 8' = + 6°.7 Corr. + 0.46
Corr. Bar. 26° 7' .14
